

## Bats

- I. What are bats?
  - Anatomy & Taxonomy
- II. Taxonomic & Biogeographic Diversity
  - see reverse side
- III. How do we catch bats to study?
  - mist nets
  - light tracking techniques
- IV. Diversity in Feeding Behavior & Trophic Level Importance
  1. Aerial Insectivores
  2. Gleaning & Fly-catching Insectivores
  3. Omnivores
  4. Carnivores- the LARGEST NEW WORLD bats
  5. Sanguinivores- VAMPIRES
  6. Piscivores
  7. Nectarivores- MAJOR rain forest pollinators
  8. Frugivores- extremely important in seed dispersal!
- V. Diversity in Reproductive Patterns
  1. Polyestrous; seasonal VAMPIRES
  2. Polyestrous; seasonal Most Other Tropical Bats
  3. Monestrous; seasonal; Some Insectivorous Bats
- VI. Diversity in Roost Site Selection
  1. Caves- most rain forest areas have caves (Karst Topo)
  2. Tree Limbs / Under Leaves
  3. Tree Trunks
  4. Tree Hollows
  5. Fallen Logs
  6. Rolled Heliconius and Banana Leaves
  7. Buildings
  8. Leaf Tents
- VII. Diversity in Social Behavior
  1. Solitary
  2. Family Groups
  3. Harems
  4. Colonies
  5. Leks
- VIII. Diversity in Temperature Regulation
  1. Constant Temperature; cannot lower (most tropical bats)
  2. Usually Constant; can lower under stress (few tropical bats)

3. Ambient at Will; estivators / hibernators (some insect.)

IX. Evolution: possible polyphyletic but evidence weak

1. Microchiroptera - most bats (from insectivores)
2. Megachiroptera - Old World Fruit Bats (from primates?)
3. Early Eocene fossil bat

Bats / Misc. Notes

CHIROPTERA:

\*second largest mammalian order (approx. 950 species)

May also exceed all other groups of mammals in number of individuals

Microchiroptera: insect eaters & carnivores

Megachiroptera: frugivores (all tropical)

Trophic Levels:

\*Insectivores

\*Frugivores

\*Nectarivores

\*Carnivores

\*Piscivores

\*Sanguivores

“Bat Adaptations”

Ability To Fly: reduction of size & mass.

wing / “hand”; fingers support flight membrane & thumb holds bat to roost

Both flight and nocturnal habit lead to niche exploitation and speciation

Echolocation: 200 “clicks” per second

frequency: 40-90 kHz (humans 20 kHz)

Co-evolution in response to echolocation:

\*noctuid moths - “fuzzbuster” / erratic flight

\*arctiid moths – “scrambler” / 30-90 kHz

Nectarivores (like nocturnal moths) visit white flowers; some lap their own urine (HCl) to help digest protein coat of pollen
